Chapter learning objectives

- Identify and cite examples of situations in which analysis of variance (ANOVA) is appropriate
- Explain the logic of hypothesis testing as applied to ANOVA
- Perform the ANOVA test, using the five-step model as a guide, and correctly interpret the results
- Define and explain the concepts of population variance, total sum of squares, sum of squares between, sum of squares within, mean square estimates
- Explain the difference between the statistical significance and the importance (magnitude) of relationships between variables

ANOVA application

- ANOVA can be used in situations where the researcher is interested in the differences in sample means across three or more categories
 - How do Protestants, Catholics, and Jews vary in terms of number of children?
 - How do Republicans, Democrats, and Independents vary in terms of income?
 - How do older, middle-aged, and younger people vary in terms of frequency of church attendance?

Extension of *t*-test

- We can think of ANOVA as an extension of t-test for more than two groups
 - Are the differences between the samples large enough to reject the null hypothesis and justify the conclusion that the populations represented by the samples are different?
- Null hypothesis, H₀
 - $H_0: \mu_1 = \mu_2 = \mu_3 = \dots = \mu_k$
 - All population means are similar to each other
- Alternative hypothesis, H₁
 - At least one of the populations means is different

Logic of ANOVA

 Could there be a relationship between age and support for capital punishment?

Support for Capital Punishment by Age Group (fictitious data)

	18–29	30–45	46–64	65+
Mean	10.3	11.0	10.1	9.9
Standard deviation	2.4	1.9	2.2	1.7

Support for Capital Punishment by Age Group (fictitious data)

	18–29	30–45	46–64	65+
Mean	10.0	13.0	16.0	22.0
Standard deviation	2.4	1.9	2.2	1.7

Between and within differences

- If the H₀ is true, the sample means should be about the same value
 - If the H₀ is true, there will be little difference between sample means
- If the H₀ is false
 - There should be substantial differences <u>between</u> sample means (between categories)
 - There should be relatively little difference <u>within</u> categories
 - The sample standard deviations should be small within groups

Likelihood of rejecting H₀

- The greater the difference <u>between</u> categories (as measured by the means)
 - Relative to the differences <u>within</u> categories (as measured by the standard deviations)
 - The more likely the H₀ can be rejected
- When we reject H₀
 - We are saying there are differences between the populations represented by the sample

Computation of ANOVA

1. Find total sum of squares (SST)

$$SST = \sum X_i^2 - N\bar{X}^2$$

2. Find sum of squares between (SSB)

$$SSB = \sum N_k (\bar{X}_k - \bar{X})^2$$

- SSB = sum of squares between categories
- $-N_k$ = number of cases in a category
- $-\bar{X}_k$ = mean of a category
- 3. Find sum of squares within (SSW)

$$SSW = SST - SSB$$

4. Degrees of freedom

$$dfw = N - k$$

- dfw = degrees of freedom within
- N = total number of cases
- k = number of categories

$$dfb = k - 1$$

- dfb = degrees of freedom between
- k = number of categories

Final estimations

5. Find mean square estimates

$$Mean square within = \frac{SSW}{dfw}$$

$$Mean square between = \frac{SSB}{dfb}$$

6. Find the F ratio

$$F(obtained) = \frac{Mean\ square\ between}{Mean\ square\ within}$$

Example

- Support for capital punishment
- Sample of 16 people who are equally divided across four age groups

Support for Capital Punishment by Age Group (fictitious data)

18	– 29	30	– 45	46	6–64	6	5+
X_i	X_i^2	X_i	X_i^2	X_i	X_i^2	X_i	X_i^2
7	49	10	100	12	144	17	289
8	64	12	144	15	225	20	400
10	100	13	169	17	289	24	576
15	225	17	289	20	400	27	729
40	438	52	702	64	1058	88	1994
$\overline{X}_k =$: 10.0	$\overline{X}_k =$: 13.0	$\overline{X}_k =$	= 16.0	$\overline{X}_k =$	= 22.0
			$\overline{\chi} =$	15.25			

Step 1: Assumptions, requirements

- Independent random samples
- Interval-ratio level of measurement

- Normally distributed populations
- Equal population variances

Step 2: Null hypothesis

- Null hypothesis, H_0 : $\mu_1 = \mu_2 = \mu_3 = \mu_4$
 - The null hypothesis asserts there is no difference between the populations
- Alternative hypothesis, H₁
 - At least one of the populations means is different

Step 3: Distribution, critical region

- Sampling distribution
 - F distribution
- Significance level
 - Alpha (α) = 0.05
- Degrees of freedom

$$- dfw = N - k = 16 - 4 = 12$$

$$- dfb = k - 1 = 4 - 1 = 3$$

- Critical F
 - -F(critical) = 3.49

Step 4: Test statistic

1. Total sum of squares (SST)

$$SST = \sum X_i^2 - N\bar{X}^2$$

$$SST = (438 + 702 + 1058 + 1994) - (16)(15.25)^2$$

 $SST = 471.04$

2. Sum of squares between (SSB)

$$SSB = \sum N_k (\bar{X}_k - \bar{X})^2$$

$$SSB = 4(10 - 15.25)^2 + 4(13 - 15.25)^2 + 4(16 - 15.25)^2 + 4(22 - 15.25)^2 = 314.96$$

3. Sum of squares within (SSW)

$$SSW = SST - SSB = 471.04 - 314.96 = 156.08$$

4. Degrees of freedom

dfw =
$$N - k = 16 - 4 = 12$$

dfb = $k - 1 = 4 - 1 = 3$

5. Mean square estimates

Mean square within =
$$\frac{SSW}{dfw} = \frac{156.08}{12} = 13.00$$

Mean square between
$$=$$
 $\frac{SSB}{dfb} = \frac{314.96}{3} = 104.99$

6. F ratio

$$F(obtained) = \frac{Mean \ square \ between}{Mean \ square \ within} = \frac{104.99}{13.00}$$

Step 5: Decision, interpret

• F(obtained) = 8.08

- This is beyond F(critical) = 3.49
- The obtained test statistic falls in the critical region, so we reject the H₀
- Support for capital punishment does differ across age groups

Example from 2016 GSS

- We know the average income by race/ethnicity
- . table raceeth [aweight=wtssall], c(mean conrinc sd conrinc n conrinc)

Race/Ethn icity	mean(conrinc)	sd(conrinc)	N(conrinc)
White	38845.61946	39157.17	1,072
Black	23243.0413	19671.53	273
Hispanic	23128.91777	21406.31	215
0ther	50156.34855	59219.9	72

- Does at least one category of the race/ethnicity variable have average income different than the others?
 - This is not a perfect example for ANOVA, because the race/ethnicity variable does not have equal numbers of cases across its categories

Example from GSS: Result

- The probability of not rejecting H_0 is small (p<0.01)
 - At least one category of the race/ethnicity variable has average income different than the others with a 99% confidence level
 - However, ANOVA does not inform which category has an average income significantly different than the others in 2016
- . oneway conrinc raceeth [aweight=wtssall]

Limitations of ANOVA

- Requires interval-ratio level measurement of the dependent variable
- Requires roughly equal numbers of cases in the categories of the independent variable
- Statistically significant differences are not necessarily important (small magnitude)
- The alternative (research) hypothesis is not specific
 - It only asserts that at least one of the population means differs from the others
